## 1 Introduction

### 2 Notation

Consider a finite population U of size N whose units can be defined by labels  $k \in \{1, 2, ..., N\}$ . Let  $S = \{s | s \subset U\}$  be the set of all possible samples. A sampling design is defined by a probability distribution p(.) on S such that

$$p(s) \ge 0$$
 for all  $s \in \mathcal{S}$  and  $\sum_{s \in \mathcal{S}} p(s) = 1$ .

A random sample S is a random vector that maps elements of S to an N vector of 0 or 1 such that P(S = s) = p(s). Define  $a_k(S)$ , for k = 1, ..., N:

$$a_k = \begin{cases} 1 & \text{if } k \in S \\ 0 & \text{otherwise.} \end{cases}$$

Then a sample can be denoted by means of a vector notation:  $\mathbf{a}^{\top} = (a_1, a_2, \dots, a_N)$ . For each unit of the population, the inclusion probability  $0 \le \pi_k \le 1$  is defined as the probability that unit k is selected into sample S:

$$\pi_k = P(k \in S) = E(a_k) = \sum_{s \in S | k \in s} p(s), \text{ for all } k \in U.$$

Let  $\boldsymbol{\pi}^{\top} = (\pi_1, \dots, \pi_N)$  be the vector of inclusion probabilities. Then,  $E(\mathbf{a}) = \boldsymbol{\pi}$ . Let also  $\pi_{k\ell}$  be the probability of selecting the units k and  $\ell$  together in the sample, with  $\pi_{kk} = \pi_k$ . The matrix of second-order inclusion probabilities is given by  $\Pi = E(\mathbf{a}\mathbf{a}^{\top})$ . The sample is generally selected with the aim of estimating some population parameters. Let  $y_k$  denote a real number associated with unit  $k \in U$ , usually called the variable of interest. For example, the total

$$Y = \sum_{k \in U} y_k$$

can be estimated by using the classical Horvitz-Thompson estimator of the total defined by

$$\widehat{Y}_{HT} = \sum_{k \in U} \frac{y_k a_k}{\pi_k}.$$
 (1)

## 3 Balanced Sampling

Usually, some auxiliary information  $\mathbf{x}_k^{\top} = (x_{k1}, x_{k2}, \dots, x_{kq}) \in \mathbb{R}^q$  regarding the population units is available. A sampling design is said to be balanced on the

auxiliary variables  $x_k$  if and only if it satisfies the balancing equations

$$\widehat{\mathbf{X}} = \sum_{k \in S} \frac{\mathbf{x}_k}{\pi_k} = \sum_{k \in U} \frac{\mathbf{x}_k a_k}{\pi_k} = \sum_{k \in U} \mathbf{x}_k = \mathbf{X}.$$

Sometimes it is not possible to select a sample that satisfies exactly the constraint. We write  $\hat{\mathbf{X}} \approx \mathbf{X}$  to notice that the sample is approximately balanced. In many applications, inclusion probabilities are such that samples have a fixed size n. A sampling design of fixed size can be viewed as balanced on only one auxiliary variable  $x_k = \pi_k$ . Indeed, we have mathematically,

$$\sum_{k \in S} \frac{x_k}{\pi_k} = \sum_{k \in S} \frac{\pi_k}{\pi_k} = n_S.$$

Let denote the set of all samples that have fixed size equal to n by

$$S_n = \left\{ \mathbf{a} \in \{0, 1\}^N \mid \sum_{k=1}^N a_k = n \right\}.$$

More generally, we write the problem of selecting a balanced sample by the following linear system:

$$\begin{cases} \sum_{k \in U} \frac{\mathbf{x}_k a_k}{\pi_k} = \sum_{k \in U} \frac{\mathbf{x}_k}{\pi_k} \pi_k \\ a_k \in \{0, 1\}, \ k \in U. \end{cases}$$

Or also written in matrix form,

$$\mathbf{A}\mathbf{a} = \mathbf{A}\boldsymbol{\pi},\tag{2}$$

where  $\mathbf{A} = \left(\frac{\mathbf{x}_1}{\pi_1}, \dots, \frac{\mathbf{x}_N}{\pi_N}\right)$ . The aim consist then of obtaining a sample  $\mathbf{a}$  that satisfies the constraints.

#### 4 Cube Method

The cube method select a sample that is balanced and respect the inclusion probabilities. The method can take equal or unequal inclusion probabilities. A each step, vector  $\boldsymbol{\pi}$  is randomly modified. The subspace induced by the linear system (??) is defined by the following,

$$A = \{\mathbf{a} \in \mathbb{R}^N | \mathbf{A}\mathbf{a} = \mathbf{A}\boldsymbol{\pi} \}$$
  
=  $\boldsymbol{\pi} + \text{Null}(\mathbf{A}),$ 

where  $\text{Null}(\mathbf{A}) = \{u \in \mathbb{R}^N | \mathbf{A}\mathbf{u} = 0\}$ . The idea is then to use a vector of the null space of  $\mathbf{A}$  such that we ensure to have martingale property of the updated inclusion probabilities. More specifically we have the following equation,

$$E_p(\boldsymbol{\pi}^t | \boldsymbol{\pi}^{t-1}) = E_p(\boldsymbol{\pi}^{t-1}), \text{ for all } t = 1, ..., N.$$

At each step, at least one component is set to 0 or 1. Matrix A is updated from the new inclusion probabilities. This step is repeated until there is only one component that is not equal to 0 or 1. Algorithm ?? present the full picture of the method. ?

#### Algorithm 1 fast flight phase of the cube Method

Calculate at first i the number of inclusion probabilities that are not equal to 0 or 1. Let  $\pi$  be equal to the i corresponding inclusion probabilities and initializing  $\pi^1$  by  $\pi$ . For  $t = 1, \ldots, N$ , we repeat:

- 1. Find  $\widetilde{\boldsymbol{\pi}}^t$  the first J entries of the inclusion probabilities  $\boldsymbol{\pi}^t$ , where  $J = \min(p+1,i)$ . Define  $\mathbf{B}$  as the J corresponding rows of the matrix A. Notice that the matrix  $\mathbf{B}$  is either a  $(p+1) \times p$  matrix or a  $i \times p$  matrix.
- 2. Find a non null vector  $\tilde{\mathbf{u}}^t$  inside of the null space of  $\mathbf{B}$ . Define  $\mathbf{u}^t$  as the expanded null vector such that  $u_k^t = 0$  for all entry that is not equal to the corresponding J values.
- 3. Calculate  $\widetilde{\lambda_1^t}$  and  $\widetilde{\lambda_2^t}$  the two greater value such that

$$\begin{array}{lll}
0 & \leqslant & \pi_k^t + \lambda_1^t u_k^t \leqslant 1, \\
0 & \leqslant & \pi_k^t - \lambda_2^t u_k^t \leqslant 1,
\end{array}$$
 for all  $k \in U$ 

Observe that  $\lambda_1^t$  and  $\lambda_2^t$  are both greater than 0.

4. Update the inclusion probabilities using the rules:

$$oldsymbol{\pi}^{t+1} = \left\{ egin{array}{ll} oldsymbol{\pi}^t + \widetilde{\lambda_1^t} \mathbf{u}^t & ext{with probability} & q_1^t \ oldsymbol{\pi}^t - \widetilde{\lambda_2^t} \mathbf{u}^t & ext{with probability} & q_2^t \end{array} 
ight.$$

where 
$$q_1^t = \widetilde{\lambda}_2^t / (\widetilde{\lambda}_1^t + \widetilde{\lambda}_2^t)$$
 and  $q_2^t = \widetilde{\lambda}_1^t / (\widetilde{\lambda}_1^t + \widetilde{\lambda}_2^t)$ .

5. Update i the number of inclusion probabilities not equal to 0 or 1.

We repeat these steps until it is no more possible to find a vector  $\widetilde{\mathbf{u}}^t$  that is inside of the null space.
